2072U Tutorial 1, 2024

## Iteration and bisection

There will be no worked-out solutions posted. **Post your solutions and questions on the dedicated Slack channel**. Working solutions should emerge from the discussion with the aid of the lecturer and the TAs. Engaging in discussions both in the tutorials and on Slack counts toward the 5% engagement credit.

In the first lecture we saw the iterative method

$$x^{(k+1)} = \phi(x^{(k)}) = \frac{1}{2} \left( x^{(k)} + \frac{a}{x^{(k)}} \right)$$

We also saw that, starting from  $x^{(0)} = 3$  with a = 5, after five iterations  $x^{(k+1)} = x^{(k)}$  up to at least 15 digits.

## Exercise A

In this exercise you will write a function to iterate the function  $\phi$ .

- (a) Write a function for  $\phi$ . Inputs should be x and a.
- (b) Write a function that iterates  $\phi$ . Inputs should be an intial point  $x^{(0)}$ , the parameter a and the maximal number of iterations  $k_{\text{max}}$ . Your function should print the successive iterates  $x^{(k)}$  to the screen.
- (c) Now modify your function so that it terminates if the maximal number of iterations is reached or if the difference between successive iterates is below some threshold, i.e. if

$$|x^{(k+1)} - x^{(k)}| < \epsilon$$

where  $\epsilon$  is an additional input.

(d) Use your function to see from which intial points the iterates converge to  $\sqrt{a}$ , depending on a. Also, try to formulate *how fast* the iterates converge. How many iterates do you need to compute to achieve a certain error  $\epsilon$ ?

## Exercise B

Read the pseudo-code for *bisection* in lecture 2.

(a) Show that if  $x^{(k+1)} = \phi(x^{(k)}) = x^{(k)}$  then  $x^{(k)}$  is the solution to

$$F(x) = x^2 - a = 0$$

- (b) Write a function for F. Input should be x and a.
- (c) Write a function that uses bisection to find an approximate solution to F(x) = 0. Inputs should be the intial boundaries  $a_0$  and  $b_0$ , the maximal number of iterations  $k_{\text{max}}$ , the error tolerance  $\epsilon_x$  and the residual tolerance  $\epsilon_f$ .
- (d) Use your function to see for which intial boundaries the iterates converge to  $\sqrt{a}$ , depending on a. Also, try to formulate *how fast* the iterates converge. How many iterates do you need to compute to achieve a certain error  $\epsilon_x$ ?

Finally, discuss which method is more efficient for approximating  $\sqrt{a}$ . Suppose every elementary computation (multiplication, division, addition, subtraction) costs you \$10, and you need to compute  $\sqrt{5}$  to 25 digits, which method would you choose?
